# Use of bioinformatics in Reproductive Sciences

### **Pinar Tulay**

Near East University Faculty of Medicine Department of Medical Genetics

# What is prenatal testing and why do it?

- Prenatal diagnosis of the common aneuploidies and monogenic disorders has been offered to pregnant women, initially to high-risk women
  - Advanced maternal age
  - Child with congenital anomalies or dysmorphology
  - Single gene disorder/ structural chromosamal abnormality
  - Consanguinity
- Invasive techniques:
  - CVS
  - Amniocentesis
  - Cordocentesis

## Types of genetic disorders

# Cell free DNA (cfDNA)

- Released through apoptosis
- Fetal
  - Placental cells (trophoblasts) in the maternal circulation
  - Released into bloodstream as small DNA fragments (150–200 bp)
- Maternal blood contains both fetal, maternal cfDNA
- Fetal cfDNA reliably detected after 7+ weeks gestation

### Assay Quality

- Lowers the limit of detection (LOD)
- Based on sequencing methodology and analysis method

### **Fetal Fraction**

Lower fetal fraction demands a lower LOD

# NIPT technology

#### NIPT 4 3 z-score 2 Chromosomal aneuploidy detection 3 5 7 9 11 13 15 17 19 21 -1 1 XXX XX Chromosomes Subchromosomal Massively deletions/duplications parallel sequencing · · ATGCCATCG· · . . . . . . . . . · · ATGCCCTCG· · Maternal plasma Bisulfite sequencing Cell-free maternal nucleic acids Maternal red blood cells Whole fetal genome sequencing 5 Diagnosis of single-gene disorders RNA-seq 5 the second Cell-free fetal nucleic acids Apoptotic trophoblasts mCGATTCGCGmCG **Fetal methylome** F 00 0 Chorionic villus AUGGUCCAGGUUA Syncytiotrophoblasts 0 S **Fetal transcriptome** 0 000 00 Cytotroph .... 0 0 0 0 Fetal circulation

R Wong FCK, Lo YMD. 2016. Annu. Rev. Med. 67:419–32

## NIPT

- It is suggested that the half-life of fetal cfDNA in maternal plasma is roughly 1 h, which means a rapid clearance after birth
  - no misinterpretation due to the presence of fetal material of previous pregnancies
- Fetus-derived DNA has been identified by a variety of fetus- specific markers, such as chromosome Y-specific sequences, epigenetic markers, and SNPs
- Limitation- presence of a high background of maternal DNA
- 5–15% of cfDNA -from the fetus
  - only a small part of the fetal cfDNA is derived from a specific chromosome
  - chromosome 21- less than 1.5% of the total number of reads is derived from this chromosome
  - 0.15% of reads is derived from the fetal chromosome 21

## Targeted approach

- Focusing the test only on the chromosomes for the common aneuploidies (trisomy 13, 18, 21, X and Y)
- It will decrease sequencing costs, as smaller numbers of reads are needed

# SNP-based targeted approach

- With parental genotypes
- Fetal genotype- heterozygous at SNP
  - Mother and father homozygous
- Fetal DNA fraction
- Feasibility- hindered
  - Parental genotypes are required

# SNP-based targeted approach

- Use of hybridization- based capture of the genomic regions of interest, followed by MPS
- PCR-amplification of 19,488 SNPs on chromosomes 13, 18, 21, X, and Y followed by MPS – requires parental genotypes
- A risk is calculated based on these results, combined with maternal and gestational age prior risks

	Hypothesis 1	Hypothesis 2	
	A:B	A:B	
SNP 1	18:7	10:10	
SNP 2	10:7	10:7	
SNP 3	20:0	20:10	
:	:	:	•••
Status	Euploid	Trisomy21	
ikelihood	100	75	

### SNP-based targeted approach

http://www.panoramatest.com.hk/snp-testing-next-generation-of-NIPT

## Cell-Free DNA Size-Based Approach

- To avoid the requirement of parental genotype information- fetal DNA fraction through the analysis of maternal plasma
- Counting of the DNA fragments in the plasma specimen
- MPS- millions of both fetal and maternal DNA fragments can be sequenced simultaneously and, each piece that maps to a discrete locus can be assigned to the chromosome from which it came.
- If fetal aneuploidy is present, there should be a relative excess or deficit for the chromosome in question.
  - difference in counts is small
  - counts need to be compared with the expected counts for euploid cases normalization with disomic chromosomes within the same test run

## Fetal Fraction Determination

CTTACCGTAATTCGGTCTAAAGTTCCAATAGGGGAG Matches chromosome 12		Counts		Counts		Counts
	1		9		17	
Matches chromosomes 1 and 6 Discard	2		10		18	
CCAGTATATTCGGTCTAGCAGTTCCAATAGGTGACT	3	1	11		19	
Increment count	4		12	2	20	
ACCGTAATTCGGTCTAAAGTTCCAATAGGGGAGCCT Matches chromosome 12 Increment count	5		13		21	
	6		14		22	
	7		15		x	
	8		16		Y	

## Fetal Fraction Determination

• Use of the difference in length between maternal and fetal cfDNA

### **Fetal Fraction Determination**

"An aneuploid sample with a lower fetal fraction has a higher probability of resulting in a false negative result."

- DNA methylation is a process by which a methyl group is added to 5' carbon of cytosine nucleotides within a CpG
- Different organs have been suggested to show variable methylation profiles, which would allow us to identify the tissue of origin analyzing the regions with differential methylation states
- Placenta-specific methylation markers methylation status changes with the progress of gestation
- Differences in methylation status between maternal and fetal DNA is used to determine the presence of trisomy 13, 18, 21 in the fetus

- A methylation-sensitive restriction enzyme digest hypomethylated maternal-derived RASSF1A promoter sequences
- Methylated fetal-derived sequences remain unaffected
  - discrimination of the methylated fetal DNA molecules from the unmethylated maternal background for the calculation of fetal DNA fraction
- Based on differentially methylated regions fetal DNA fraction in a plasma sample

### 1. Differentially methylated markers

- Massively parallel bisulfite sequencing estimate the fetal DNA fraction according to the ratio of fetal-derived DNA molecules within differentially methylated regions
- Sodium bisulfite treatment converts cytosine into uracil, while methylated cytosine is not affected.
- After MPS (where uracil is read as a thymine rather than a cytosine nucleotide), methylated cytosine nucleotides can be identified by comparing the modified DNA to the original reference sequence.

• Limitation: bisulfite conversion or digestion with methylationsensitive restriction enzymes may affect the accuracy; genome-wide bisulfite sequencing is too expensive

# NIPD for single gene disorders

- Single gene disorders- DIAGNOSIS
- Testing from paternally inherited and *de novo* mutation for many rare conditions
- Genetic maps from paternal and maternal DNA- fetal genome could be deduced

# NIPD for recessive disorders

- Maternal inheritance, the analysis of the sequencing data is relatively more complicated.
  - fetal DNA is a minority in maternal plasma
  - analysis requires a quantitative approach based on SNP sites that are homozygous in the father and heterozygous in the mother
- DNA samples from the affected child and parents are analyzed to determine the haplotype structure of SNPs flanking the disease gene

Possible Fetal Genotypes

# Reasons of false positives and false negatives

### • False Negative:

- Too little fetal DNA (usually reported as failed)
- Mosaicism
- False positive:
- Mosaicism
- Vanishing twin
- Maternal sex chromosome abnormality
- Neoplasia apoptosis of cancer cells, aneuploidy common

## Reasons for False-Negative Results

- Low Fetal Fraction
- False-negative rate increases with lower fetal fraction
- Threshold for the fetal fraction for accurate testing is around 4%
- The fetal fraction can be influenced by several factors.
- The four main factors are
  - (1) maternal weight and/or BMI- lower fetal fraction
  - (2) gestational age- before 7<sup>th</sup> week of gestation, higher risk
  - (3) multiple gestations- lower fetal fraction
  - (4) fetal aneuploidy-? aneuploid fetus has lower fetal fraction

# Reasons for False-Negative/ Positive Results

- True mosaicism Presence of two or more karyotypically different cell lines in both the placenta and the fetus.
  - false positive or a false negative depending on the origin of the cfDNA
- Confined placental mosaicism Presence of two or more karyotypically different cell lines that are confined to the placenta and not present in the fetus.
  - false positive
  - CPM is reported to be present in 1–2% of first trimester placentas
  - For chromosomes other than chromosome 21, 18, or 13, CPM is more common
- Fetal mosaicism Presence of two or more karyotypically different cell lines that are present in the fetus but not present in the placenta.
  - false negative

## Reasons for False-Negative Results

- Twin Pregnancies
- The fetal fraction per fetus in twin pregnancies is 30–50% lower than in singleton pregnancies
- More difficult to analyze because each fetus will release different amounts of cfDNA
- NIPT is not recommended for these pregnancies.

## Reasons for False-Positive Results

- Maternal Findings: Chromosomal Abnormalities
- An aberrant NIPT result can also be the consequence of an abnormal karyotype or cell line in the pregnant woman.
- This finding can mistakenly be interpreted as an abnormal finding in the fetus.
- Triple X syndrome (47, XXX) is a relatively common chromosome abnormality (the prevalence is about 1 in 1000) which often goes undiagnosed and could lead to an abnormal NIPT result

## Reasons for False-Positive Results

- Maternal Findings: Malignancy
- NIPT can incidentally detect an occult maternal malignancy.
- The incidence ranges from 0.07% to 0.1% for all malignant tumors, affecting approximately 1 in 1000 pregnancies
- The most common malignancies associated with pregnancy include cervical cancer, breast cancer, malignant melanoma, lymphomas, leukemias, ovarian cancer, and colorectal cancer

## Reasons for False-Positive Results

### • Vanishing Twin

• Sometimes during an ongoing multiple pregnancy the twin fetus dies in utero, resulting in an apparent singleton pregnancy.

# Post-test Counseling:

- If a positive NIPT result:
  - Remember False Positives occur
  - Refer for genetic counseling
  - Always offer invasive testing for confirmation
  - If parents decline invasive testing, postnatal confirmation should be completed
- If a Negative NIPT result:
  - Remember False Negatives occur especially in higher risk pregnancies
  - Always offer invasive testing if parents want to "know for sure"
- "The tests should not be considered to be fully diagnostic and therefore are not a replacement for amniocentesis and CVS"

Final Report			

### Test Result

### Negative

This specimen showed an expected representation of chromosome 21, 18 and 13 material. Y chromosomal material was detected in this sample.

### Interpretation

These results are consistent with an expected amount of fetal chromosome 21, 18 and 13 material. Y chromosomal material was detected, consistent with a male fetus. Clinical correlation is suggested.

### About the Test

The MaterniT21 PLUS test analyzes circulating cell-free DNA extracted from a maternal blood sample.<sup>2</sup> The test is indicated for use in pregnant women with increased risk for chromosomal aneuploidy. Samples are also assessed for the presence of Y chromosomal material. However, sex chromosome aneuploidy is not designated by this result.

### Additional Perspective

DNA test results do not provide a definitive genetic risk in all individuals. While results of this testing are highly accurate, infrequent errors may be due to unusual DNA sequences in the DNA analyzed or other causes. Based on the methodology and known performance characteristics, multiple gestations are not expected to influence test results.

### Disclaimer

This LDT was developed and its performance characteristics determined by Sequenom Center for Molecular Medicine. It has not been cleared or approved by the LLS Food and Drug

# What is Preimplantation Genetic Diagnosis?

- Preimplantation genetic diagnosis (PGD) is applied to couples at risk of transmitting an inherited disease or chromosomal imbalance to their offspring.
- Couples who have already been diagnosed with a
  - single gene disorder or
  - a chromosome imbalance

can opt for PGD to select an embryo free from the mutation or an embryo with a balanced karyotype prior to implantation and pregnancy.

## Preimplantation genetic screening

- To try and improve pregnancy rates
- Advanced maternal age
- Prior pregnancy /child chromosomally abnormal
- Multiple implantation failures (≥2 failed IVF)
- Recurrent miscarriage (≥2 miscarriages)
- Severe male factor (low sperm count)

• Social sexing

## How is PGT performed?

**Ovarian Stimulation** 

IVF

Blastomere Biopsy on Day 3 or 5/6

Transfer of Unaffected Embryo Outcome Chromosomally Normal Baby

**Genetic Analysis** 

### **Preimplantation Genetic Testing**

A procedure used in conjunction with *in vitro* fertilization (IVF) to screen for **specific genetic** or **chromosomal abnormalities** before transferring the fertilized eggs into the mother.

### •PGS (Preimplantation Genetic

Screening)

•(Numerical or structural chromosomal

abnormalities)

### •PGD for Monogenic Diseases (PGD)

- •PGD for late onset disorders
- •PGD for inherited cancer predisposition
- •with or w/o HLA typing

### maternal line

Your mitochondrial DNA determines your maternal haplogroup. What is a haplogroup?

#### Map History Haplogroup Tree

#### Maternal Haplogroup: U5

Locations of haplogroup U5 circa 500 years ago, before the era of intercontinental travel.

Haplogroup: U5, a subgroup of U

Age: 40,000 years

Region: Europe, Near East, North Africa

Populations: Basques, Saami (Lapps) of northern Scandinavia

Highlight: Though primarily a European haplogroup, U5 was recently found in mitochondrial DNA extracted from the remains of a 6th-century AD Chinese chieftain.

#### **Your Family and Friends**

Haplogroup U5 arose among early colonizers of Europe around 40,000 years ago; maternal descendants of those early colonizers persist in the region to this day. After the last ice Age two subgroups of U5 expanded across Europe and into northern Africa and the Near East. Today, one subgroup, U5b1b, is shared by groups as diverse as the northern African desertdwelling Berbers and the Scandinavian Arctic-dwelling Saami, also known as the Lapps.

### paternal line

Your Y chromosome DNA determines your paternal haplogroup. What is a haplogroup?

Map History Haplogroup Tree

#### Paternal Haplogroup: E3b1a

Locations of haplogroup E3b1a circa 500 years ago, before the era of intercontinental travel.

Haplogroup: E3b1a, a subgroup of E3b

Age: 14,000 years

Region: Northern Africa, Southern Europe

Populations: Berbers, Iberlans, Balkans

Highlight: Two different migrations brought E3b1a into Europe.

#### Your Family and Friends

E3b is most common in northern Africa and southern Europe. It arose about 17,000 years ago in eastern Africa and spread into the Mediterranean region after the Ice Age. E3b1a, a subgroup of E3b, expanded out of the Near East 8,000 years ago into northern Africa and southern Europe. Today it is one of the most common haplogroups in those regions.
